NANNY-APP - CI/CD AND APK RELEASE PLAN

Task 2 implementation evidence | Version 1.0 | 19 October 2026

1. PIPELINE

Commit or pull request -> PHP/security checks -> Android tests/lint/build -> review and tag -> signed APK GitHub Release.

Every change is checked by GitHub Actions. Releases are created from tags so the source, APK and notes remain traceable.

2. GITHUB ACTIONS CHECKS

CI: PHP/security suite, Android debug build, JVM tests, lint and unsigned release compilation. Output: test summary and build artifacts.

Android release: JDK 21, Android SDK 36, HTTPS API validation, signing and APK signature verification. Output: NannyApp.apk GitHub asset.

Supabase migration: protected migration endpoint and health check.

3. REQUIRED REPOSITORY CONFIGURATION

NANNYAPP_RELEASE_KEYSTORE_BASE64

NANNYAPP_RELEASE_KEYSTORE_PASSWORD

NANNYAPP_RELEASE_KEY_ALIAS

NANNYAPP_RELEASE_KEY_PASSWORD

Set NANNYAPP_RELEASE_API_URL to an HTTPS API ending in /api/. Never commit secrets or the signing keystore.

4. RELEASE PROCEDURE

1. Run CI and confirm tests, lint and release compilation pass.
2. Create and push an annotated version tag such as v1.0.2.
3. GitHub Actions builds, signs and verifies the APK and attaches it.
4. Set NANNYAPP_APK_URL on the web host to the latest-release URL.
5. Install on a real Android phone and record the result.

5. QUALITY AND ROLLBACK

Automated checks pass; API is HTTPS; migrations are applied; signature verifies; registration, verification, login and settings work on a real device; and the previous GitHub release remains available for rollback.

6. DEMONSTRATION EVIDENCE

Show the green Actions run, GitHub Release APK asset, website download page, phone installation, registration/login, database/API records and a voice-over explaining the release pipeline.
